A new method is described for the study of DNA language employing the communicative strength of music. An algorithm was created to "translate" codons into musical notes. The analysis of the musical transcriptions of DNA sequences suggests the presence of some structural features of DNA language hidden in human and mouse interferon α1 genes.

Key terms: *DNA, information, language, structure.*

INTRODUCTION

During the evolution of life, DNA molecules of increasing complexity appeared. Evolutionary pressure, through selection, must have preserved from survival many of such DNA molecules, thus avoiding a simple random-base organization of the genome of surviving organisms. This non-random organization of the genome must have left a structural imprinting in the DNA language, preserving some structural features.

Some authors have emphasized the role that palindromes play in the organization of genomic nucleotide sequences and the variety of functions these sequences are known to be involved in (4). Several grammatical rules have been applied to the formulation of DNA language showing that there is at least some degree of organization in the nucleotide sequences found in many organisms (2-3).

Attempting to find some features in the pattern of nucleotide and amino acid sequences, we have created an algorithm to assign musical notes to all different codons. Employing this algorithm we have "translated" into music human and mouse interferon (IFN) α1 genes.

Through this simple method employing the communicative strength of music, we have found that there are some syntactical structures in the DNA language and have revealed some properties of these structures. The method could be employed for the study of the DNA language.

METHODS

An algorithm was created to assign musical notes to all different codons.

Codons were denoted as $X_nY_nZ_n$ and musical notes as N_n.

Every aminoacid

$$(aa)_{n1n2}=X_\beta Y_\beta Z_\beta=N_{n2}N_{n1}=N_{n2}Y_\beta Z_\beta Z_\tau$$

for every $1\leq n1\leq 6$; $1\leq n2\leq 20$; $1\leq \alpha, \beta, \tau\leq 4$

If by definition, aminoacid

$(aa)_{1n2}=X_\alpha Y_\alpha Z_\alpha=N_{n2}$, then

if $n1=1$, $N_{n2}N_{n1}=N_{n2}$

The assignment of the musical note for the first codon for every aminoacid (N_1, N_2, ..., N_{20}) was arbitrary and corresponded to the order given in Table I.

Abbreviations: **D** = Do, **R** = Ray, **M** = Me, **F** = Fah, **S** = Solh, **L** = Lah, **T** = Te.
* For some aminoacid codons, the mathematical notation is shown as an example.
** The mathematical notation for the musical note corresponding to the first codon for some aminoacids is shown in parenthesis as an example.

Employing the data on Table I and the proposed algorithm, as an example, let us find the musical notes that correspond to the codons CGC and GAG coding for aminoacids Arg and Glu respectively:

$(aa)_{22} = CGC = N_2GCZ_\tau = R(aa)_{11} = RN_1 = RDR$

$(aa)_{27} = GAG = N_7AGZ_\tau = FS(aa)_{12} = FSN_2 = FSR$

The sequences employed in this report corresponded to the human interferon (HuIFN) -α1 (6) and mouse interferon (MuIFN) -α1 (7) genes.

The random DNA sequence was generated by making the following substitutions in the musical translation of the MuIFN-α1 gene: MexDo; RayxSoh; LahxFah; DoSohxMe; TeTexRay; FahDoxLah.

Musical scores were prepared in a rhythm of waltz.

RESULTS AND DISCUSSION

The problem of studying and understanding the DNA language has focused the attention of many researchers.

Languages of the world belong to two major groups, Indo-Aryan and Ural-Altaic. Yet, the principle of having to have syntactical structures remains the same. Music, as a language, is also governed by syntactical structures. DNA and protein aminoacid sequences are also for communication. Therefore, if considering communication as an evolutionary process, it will not be a surprise if human languages, including music, learned the art of communication from these ancient informational molecules.

In an attempt to try to find some features in the pattern of nucleotide and aminoacid sequences, we have created an algorithm to assign musical notes to all different codons. Employing this algorithm we have "translated" into music human and mouse IFN-α1 genes (Figs 1 and 2). Music, as a highly expressive way of communication, brings the possibility to detect structures otherwise hidden for the human eye.

As a control for randomly originated structures, we created a random DNA sequence by randomly making some arbitrary substitutions in the sequence of the MuIFN-α1 gene (Fig 3). The sequence obtained was compared to the EMBL sequence data bank (release May 20, 1993) employing the program BLASTN 1.2.5 (1) and no significant homologies were found, thus indicating that the sequence obtained was not similar to any known DNA sequence.

Fig 1. Nucleotide and aminoacid sequences of HuIFN-α1, with corresponding musical notes for each codon. Abbreviations described in Table I.

After the application of the algorithm for translating into music the DNA sequences, resulting arrays of musical notes were organized in scores (Figs 4-6). Melodies that corresponded to the sequences of Hu and Mu IFN-α1 genes resembled a Re-dorical mode and revealed the existence of some syntactical structures in the DNA language, such as palindromic and repetitive segments, that carried numerous overlapping patterns, used for communicating to other molecules and structures the details of specific interactions and entire processes. For the randomly generated sequence, no structured melody could be found.

The meaning of these messages is, in most of the cases, unknown. In fact, the method employed by us is not intended for decod-

ifying such messages. As U Eco mentioned in his "Treatise of General Semiotic" (5), music appears as a semiotic system in which any expressive situation can be interpreted in different ways. Through the method described here, we can only search for syntactical structures and some features of such structures by analyzing the scores and the melodies obtained from these scores, but we can not help in trying to understand them.

The method can be employed also to generate musical scores from the available sequence data bank. These scores can be employed to study gene families and the evolution of conserved genes by searching for homology in the respective melodies'

modes and calculating the similarity between sequences by correlating their scores as a mean to detect both closely and distantly related sequences.

We have found that the genome appears organized as a score of necessary messages, although we do understand only few of them.

ACKNOWLEDGEMENTS

The authors will like to thank N García and S García for preparing musical scores. N García was also of invaluable help for playing and recording scores. Scores were kindly revised by Mrs C Rodríguez and Mr G Silva.
